WEAKLY MIXING GROUP ACTIONS: A BRIEF SURVEY AND AN EXAMPLE

V. BERGELSON, A. GORODNIK

Dedicated to Anatole Katok on the occasion of his 60th birthday.

1. INTRODUCTION

At its inception in the early 1930’s, ergodic theory concerned itself with continuous one-parameter flows of measure preserving transformations ([Bi], [vN1], [KvN], [Ho1], [Ho2]). Soon it was realized that working with $\mathbb{Z}$-actions rather than with $\mathbb{R}$-actions, has certain advantages. On the one hand, while the proofs become simpler, the results for $\mathbb{R}$-actions can often be easily derived from those for $\mathbb{Z}$-actions (see, for example, [Ko]). On the other hand, dealing with $\mathbb{Z}$- (or even with $\mathbb{N}$-) actions extends the range of applications to measure preserving transformations which are not necessarily embeddable in a flow. Weakly mixing systems were introduced (under the name dynamical systems of continuous spectra) in [KvN]. By the time of publishing in 1937 of Hopf’s book [Ho3], the equivalence of the following conditions (which, for convenience, we formulate for $\mathbb{Z}$-actions) was already known. It is perhaps worth noticing that, while in most books either (i) or (ii) below is taken as the “official” definition of weak mixing, the original definition in [KvN] corresponds to the condition (vi).

Theorem 1.1. Let $T$ be an invertible measure-preserving transformation of a probability measure space $(X, \mathcal{B}, \mu)$. Let $U_T$ denote the operator defined on the space of measurable functions by $(U_T f)(x) = f(Tx)$. The following conditions are equivalent:

(i) For any $A, B \in \mathcal{B}$,
\[
\lim_{N \to \infty} \frac{1}{N} \sum_{n=0}^{N-1} \langle \mu(A \cap T^{-n}B) - \mu(A)\mu(B) \rangle = 0.
\]

(ii) For any $A, B \in \mathcal{B}$, there is a set $P \subset \mathbb{N}$ of density zero such that
\[
\lim_{n \to \infty, n \notin P} \mu(A \cap T^{-n}B) = \mu(A)\mu(B).
\]

(iii) $T \times T$ is ergodic on the Cartesian square of $(X, \mathcal{B}, \mu)$.

(iv) For any ergodic probability measure preserving system $(Y, \mathcal{D}, \nu, S)$, the transformation $T \times S$ is ergodic on $X \times Y$.

(v) If $f$ is a measurable function such that for some $\lambda \in \mathbb{C}$, $U_T f = \lambda f$ a.e., then $f = \text{const}$ a.e.

(vi) For $f \in L^2(X, \mathcal{B}, \mu)$ with $\int_X f d\mu = 0$, consider the representation of the positive definite sequence $(U^n_T f, f), n \in \mathbb{Z}$, as a Fourier transform of a measure $\nu$ on $\mathbb{T} = \mathbb{R}/\mathbb{Z}$:
\[
\langle U^n_T f, f \rangle = \int_{\mathbb{T}} e^{2\pi i n \xi} \nu d\xi, \quad n \in \mathbb{Z}
\]

(this representation is guaranteed by Herglotz theorem, see [He]). Then $\nu$ has no atoms.

Remark 1.2. It is not too hard to show that condition (i) can be replaced by the following more general condition:

*The first author was supported by the NSF Grants DMS-0070566 and DMS-0345350.
(i') For any \( A, B \in \mathcal{B} \) and any sequence of intervals \( I_N = [a_N + 1, a_N + 2, \ldots, b_N] \subset \mathbb{Z} \), \( N \geq 1 \), with \( |I_N| = b_N - a_N \to \infty \), one has
\[
\lim_{N \to \infty} \frac{1}{|I_N|} \sum_{n=a_N+1}^{b_N} |\mu(A \cap T^{-n}B) - \mu(A)\mu(B)| = 0.
\]
Condition (i'), in its turn, is equivalent to a still more general condition in which the sequence of intervals \( \{I_N\}_{N \geq 1} \) is replaced by an arbitrary Følner sequence, i.e. a sequence of finite sets \( F_N \subset \mathbb{Z} \), \( N \geq 1 \), such that for any \( a \in \mathbb{Z} \),
\[
\frac{|(F_N + a) \cap F_N|}{|F_N|} \to 1 \quad \text{as} \quad N \to \infty.
\]
This more general form of condition (i') makes sense for any (countably infinite) amenable group and, as we shall see below (cf. Theorem 1.6), can be used to define the notion of weak mixing for actions of amenable groups.

**Remark 1.3.** If \( (X, \mathcal{B}, \mu) \) is a separable space (which will be tacitly assumed from now on), the condition (ii) can be replaced by the following condition (see Theorem I in [KvN]):

(ii') There exists a set \( P \subset \mathbb{N} \) of density zero such that for any \( A, B \in \mathcal{B} \), one has
\[
\lim_{n \to \infty} \frac{\mu(A \cap T^{-n}B) - \mu(A)\mu(B)}{P_n} = 0.
\]

Condition (ii) in Theorem 1.1 indicates the subtle but significant difference between weak and strong mixing: while for strong mixing one has \( \mu(A \cap T^{-n}B) \to \mu(A)\mu(B) \) as \( n \to \pm \infty \) for any pair of measurable sets, a weakly mixing system which is not strongly mixing is characterized by the absence of mixing for some sets along some rarefied (i.e. having density zero) sequence of times. Although the first examples of weakly but not strongly mixing measure preserving transformations were quite complicated, numerous classes of measure preserving systems that satisfy this property are known by now. For instance, one can show that the so-called interval exchange transformations (IET) are often weakly mixing ([KS], [V]). On the other hand, A. Katok proved in [Ka] that the IET are never strongly mixing. It should be also mentioned here that weakly mixing measure preserving transformations are “typical”, whereas strongly mixing ones are not (see, for example, [H]). Before moving our discussion to weakly mixing actions of general groups, we would like to formulate some more recent results which exhibit new interesting facets of the notion of weak mixing.

**Theorem 1.4.** Let \( T \) be an invertible measure-preserving transformation of a probability measure space \( (X, \mathcal{B}, \mu) \). The following conditions are equivalent:

(i) The transformation \( T \) is weakly mixing,

(ii) Weakly independent sets are dense in \( \mathcal{B} \). (Here a set \( A \in \mathcal{B} \) is weakly independent if there exists a sequence \( n_1 < n_2 < \cdots \) such that the sets \( T^{-n_i}A, i \geq 1 \), are mutually independent),

(iii) For any \( A \in \mathcal{B} \) and \( k \in \mathbb{N}, k \geq 2 \), one has
\[
\lim_{N \to \infty} \frac{1}{N} \sum_{n=0}^{N-1} \mu(A \cap T^{-n}A \cap T^{-2n}A \cap \cdots \cap T^{-kn}A) = (\mu(A))^{k+1}.
\]

(iv) For any \( k \in \mathbb{N}, k \geq 2 \), any \( f_1, f_2, \ldots, f_k \in L^\infty(X, \mathcal{B}, \mu) \), and any non-constant polynomials \( p_1(n), p_2(n), \ldots, p_k(n) \in \mathbb{Z}[n] \) such that for all \( i \neq j \), \( \deg(p_i - p_j) > 0 \), one has
\[
\lim_{N \to \infty} \frac{1}{N} \sum_{n=0}^{N-1} f_1(T^{p_1(n)}x)f_2(T^{p_2(n)}x) \cdots f_k(T^{p_k(n)}x) = \int f_1 d\mu \int f_2 d\mu \cdots \int f_k d\mu
\]
in \( L^2 \)-norm.

**Remark 1.5.** Condition (ii) is due to U. Krengel (see [Kr] for this and related results). Condition (iii) plays a crucial role in Furstenberg’s ergodic proof of Szemerédi’s theorem on arithmetic progressions (see [F1] and [F2]). Criterion (iv) was obtained in [Be1]. Similarly to the “linear” case (iii), the
condition (iv) (or, actually, some variations of it) plays an important role in proofs of polynomial extensions of Szemerédi’s theorem (see [BeL1], [BeM1], [BeM2], [L]). Note that the assumption $k \geq 2$ in (iii) and (iv) is essential. Indeed, for $k = 1$ condition (ii) expresses just the ergodicity of $T$, whereas for $k = 1$, condition (iv) is equivalent to the assertion that all non-zero powers of $T$ are ergodic. The following equivalent form of condition (iv) is, however, both true and nontrivial already for $k = 1$ (cf. condition (ii’ in Remark 1.3):

(iv’) For any $k \geq 1$ and any nonconstant polynomials $p_1(n), \ldots, p_k(n) \in \mathbb{Z}[n]$ such that for all $i \neq j$, $\deg(p_i - p_j) > 0$, there exists a set $P \subset \mathbb{N}$ having zero density such that for any sets $A_0, \ldots, A_k \in \mathcal{B}$, one has

$$
\lim_{n \to \infty, n \notin P} \mu(A_0 \cap T^{p_1(n)} A_1 \cap \cdots \cap T^{p_k(n)} A_k) = \mu(A_0) \mu(A_1) \cdots \mu(A_k).
$$

Theorems 1.1, 1.4, and numerous appearances and applications of weakly mixing one-parameter actions in ergodic theory hint that the notion of weak mixing could be of interest and of importance for actions of more general groups. One wants, of course, not only to be able to come up with a definition (this is not too hard: for example, condition (iii) in Theorem 1.1 makes sense for any group action), but also to be able to have, similarly to the case of one-parameter actions, many diverse equivalent forms of weak mixing including those which pertain to independence and higher degree mixing properties of the type given in Theorem 1.4.

Let $(T_g)_{g \in G}$ be a measure preserving action of a locally compact group $G$ on a probability measure space $(X, \mathcal{B}, \mu)$. If $G$ is amenable, one can replace condition (i) in Theorem 1.1 (or, rather, condition (i’) in Remark 1.2) by the assertion that the averages of the expressions $|\mu(A \cap T_g B) - \mu(A) \mu(B)|$ taken along any Følner sequence in $G$ converge to zero. If $G$ is noncommutative, one also has to replace condition (v) by the assertion that the only finite-dimensional subrepresentation of $(U_g)_{g \in G}$ (where $U_g$ is defined by $(U_g f)(x) = f(T_g^{-1} x)$, $f \in L^2(X, \mathcal{B}, \mu)$) is the restriction to the subspace of constant functions. Dye has shown in [D] that under these modifications the conditions (i), (iii), and (v) in Theorem 1.1 are equivalent. Dye’s results are summarized in the following theorem (cf. [D], Corollary 1, p. 129). Again, for the sake of notational convenience, we state the theorem for the case of a countable group $G$.

**Theorem 1.6.** Let $(T_g)_{g \in G}$ be a measure preserving action of a countable amenable group $G$ on a probability measure space $(X, \mathcal{B}, \mu)$. Then the following conditions are equivalent:

(i) For every Følner sequence $(F_n)_{n=1}^\infty$ in $G$ and any $A, B \in \mathcal{B}$, one has

$$
\lim_{n \to \infty} \frac{1}{|F_n|} \sum_{g \in F_n} |\mu(A \cap T_g B) - \mu(A) \mu(B)| = 0.
$$

(ii) The only finite dimensional subrepresentation of $(U_g)_{g \in G}$ is its restriction to the space of constant functions.

(iii) The diagonal action of $(T_x \times T_g)_{x \in G}$ on the product space $(X \times X, \mathcal{B} \otimes \mathcal{B}, \mu \otimes \mu)$ is ergodic (i.e. has no nontrivial invariant sets).

**Remark 1.7.** As a matter of fact, it is not too hard to show that conditions (ii) and (iii) in Theorem 1.6 are equivalent for any locally compact noncompact second countable group. See, for instance, [Moore], Proposition 1, p. 157.

A measure preserving system $(X, \mathcal{B}, \mu, T)$ is called a system with *discrete spectrum* if $L^2(X, \mathcal{B}, \mu)$ is spanned by the eigenfunctions of the induced unitary operator $U_T$. It is not hard to show that the condition (v) in Theorem 1.1 implies that a measure preserving system $(X, \mathcal{B}, \mu, T)$ is weakly mixing if and only if it does not have a nontrivial factor which is a system with discrete spectrum. Remark 1.7 hints that a natural generalization of this fact to general group actions holds as well. (A measure preserving action of a group $G$ on a probability space $(X, \mathcal{B}, \mu)$ has discrete spectrum if $L^2(X, \mathcal{B}, \mu)$ is representable as a direct sum of finite-dimensional invariant subspaces.)
In [vN2] and [H] von Neumann and Halmos have shown that an ergodic one-parameter measure preserving action has discrete spectrum if and only if it is conjugate to an action by rotations on a compact abelian group. Again, this result has a natural extension to general group actions. See [Mac] for details and further discussion.

The duality between the notion of weak mixing and discrete spectrum extends to the relative case, namely, to the situation where one studies the properties of a system relatively to its factors. The theory of relative weak mixing is in the core of highly nontrivial structure theory developed by H. Furstenberg in the course of his proof ([F1]) of Szemerédi theorem. See also [FK1] and [F2], Chapter 6.

In [Z1] and [Z2] the duality between weak mixing and discrete spectrum is generalized to extensions of general group actions. In particular, Zimmer established a far reaching “relative” version of Mackey’s results on actions with discrete spectrum.

A useful interpretation of condition (i) in Theorem 1.6 is that if $\mathcal{C}$ is a compact abelian group. Again, this result has a natural extension to general group actions. See [Eb]. By a theorem of Ryll-Nardzewski (see [Eb]), for every locally compact group which acts in a weakly mixing fashion on a probability space $(X, \mathcal{B}, \mu)$, the set

$$R_{A,B} = \{ g \in G : |\mu(A \cap T_g B) - \mu(A)\mu(B)| < \varepsilon \}$$

is large in the sense that it has density 1 with respect to any Følner sequence $(F_n)_{n=1}^\infty$:

$$\lim_{n \to \infty} \frac{|R \cap F_n|}{|F_n|} = 1.$$  

A natural question that one is led to by this fact is whether there is a similar characterization of the sets $R_{A,B}$ in the case when $G$ is not necessarily amenable.

It turns out that for every locally compact group which acts in a weakly mixing fashion on a probability space, the set $R_{A,B}$ is always “conull”, and in more than one sense. One approach, undertaken in [BeRo], is to utilize the classical fact that functions of the form $\psi(g) = \mu(A \cap T_g A)$ are positive definite. This implies that such $\psi(g)$, as well as a slightly more general functions of the form $\phi(g) = \mu(A \cap T_g B)$, are weakly almost periodic (see [Eb]). By a theorem of Ryll-Nardzewski (see [R-N]), there is a unique invariant mean on the space WAP$(G)$ of weakly almost periodic functions. Denoting this mean by $M$ and assuming that for every $A, B \in \mathcal{B}$, the function $g \mapsto \mu(A \cap T_g B)$ is continuous on $G$, let us call the action $(T_g)_{g \in G}$ weakly mixing if for all

$$f_1, f_2 \in L_0^2(X, \mathcal{B}, \mu) \overset{def}{=} \{ f \in L^2(X, \mathcal{B}, \mu) : \int_X f \, d\mu = 0 \},$$

one has

$$M \left( \int_X f_1(x) f_2(T_g x) \, d\mu(x) \right) = 0.$$  

**Theorem 1.8.** ([BeRo], Theorem 4.1) Let $(T_g)_{g \in G}$ be a measure preserving action of a locally compact second countable group $G$ on a probability space $(X, \mathcal{B}, \mu)$. The following are equivalent:

(i) $(T_g)_{g \in G}$ is weakly mixing.

(ii) For every $f_1, f_2 \in L^2(X, \mathcal{B}, \mu)$,

$$M \left( \int_X f_1(x) f_2(T_g x) \, d\mu(x) - \int f_1 \, d\mu \int f_2 \, d\mu \right) = 0.$$  

(iii) For every $f_0, \ldots, f_n \in L_0^2(X, \mathcal{B}, \mu)$ and $\varepsilon > 0$, there exists $g \in G$ with

$$\left| \int_X f_0(x) f_i(T_g x) \, d\mu(x) \right| < \varepsilon, \quad i = 1, \ldots, n.$$  

(iv) For every $g_1, \ldots, g_n \in G$, $f \in L_0^2(X, \mathcal{B}, \mu)$, and $\varepsilon > 0$, there exists $g \in G$ such that

$$\left| \int_X f(T_g x) f(T_{g_i} x) \, d\mu(x) \right| < \varepsilon, \quad i = 1, \ldots, n.$$
(v) For all \( F \in L^2(X, \mathcal{B}, \mu) \), where \( F \) is not equivalent to a constant, the set \( \{ f(T_g x) : g \in G \} \) is not relatively compact in \( L^2(X, \mathcal{B}, \mu) \).

(vi) \( L^2(X, \mathcal{B}, \mu) \) contains no nontrivial finite dimensional invariant subspaces of \( (U_g)_{g \in G} \).

(vii) \( (T_g, T_q)_{g \in G} \) is ergodic.

(viii) \( (T_g, T_q)_{g \in G} \) is weakly mixing.

We shall describe now one more approach to weak mixing for general group actions (see [Be3], Section 4, for more details and discussion). Let \( G \) be a countably infinite, not necessarily amenable discrete group. For the purposes of the following discussion it will be convenient to view \( \beta G \), the Stone–Čech compactification of \( G \), as the space of ultrafilters on \( G \), i.e. the space of \( \{0,1\} \)-valued finitely additive probability measures on the power set of \( G \). Since elements of \( \beta G \) are \( \{0,1\} \)-valued measures, it is natural to identify each \( p \in \beta G \) with the set of all subsets having \( p \)-measure 1, and so we shall write \( A \in p \) instead of \( p(A) = 1 \). (This explains the terminology: ultrafilters are just maximal filters.) Given \( p, q \in G \), one defines the product \( p \cdot q \) by

\[
A \in p \cdot q \iff \{ x : Ax^{-1} \in p \} \in q.
\]

The operation defined above is nothing but convolution of measures, which, on the other hand, is an extension of the group operation on \( G \). (Note that elements of \( G \) are in one-to-one correspondence with point masses, the so-called principal ultrafilters.) It is not hard to check that the operation introduced above is associative and that \( (\beta G, \cdot) \) is a left topological compact semigroup (which, alas, is never a group for infinite \( G \).) For a comprehensive treatment of topological algebra in the Stone–Čech compactification, the reader is referred to [HiS]. By a theorem due to R. Ellis [El], any compact semigroup with a left continuous operation has an idempotent. (There are, actually, plenty of them since there are \( 2^N \) disjoint compact semigroups in \( \beta G \).) Idempotent ultrafilters find numerous applications in combinatorics (see, for example, [Hi] and [HiS], Part 3) and also are quite useful in ergodic theory and topological dynamics (see, for example, [Be2], [Be3]).

Given an ultrafilter \( p \in \beta G \) and a sequence \( (x_g)_{g \in G} \) in a compact Hausdorff space, one writes

\[
p \cdot \lim_{g \in G} x_g = y
\]

if for any neighborhood \( U \) of \( y \), one has

\[
\{ g \in G : x_g \in U \} \in p.
\]

Note that in compact Hausdorff spaces \( p \)-limit always exists and is unique.

The following theorem, which is an ultrafilter analogue of Theorem 1.7 from [FK2], illustrates the natural connection between idempotents in \( \beta G \) and ergodic theory of unitary actions.

**Theorem 1.9.** Let \( (U_g)_{g \in G} \) be a unitary action of a countable group \( G \) on a Hilbert space \( \mathcal{H} \). For any nonprincipal idempotent \( p \in \beta G \) and any \( f \in \mathcal{H} \) one has

\[
p \cdot \lim_{g \in G} U_g f = Pf \quad \text{(weakly)}
\]

where \( P \) is the orthogonal projection on the subspace \( \mathcal{H}_p \) of \( p \)-rigid elements, that is, the space defined by

\[
\mathcal{H}_p = \{ f : p \cdot \lim_{g \in G} U_g f = f \}.
\]

Theorem 1.9 has a strong resemblance to the classical von Neumann’s ergodic theorem. In both theorems a generalized limit of \( U_g f \), \( g \in G \), (in case of von Neumann’s theorem this is the Cesáro limit) is equal to an orthogonal projection of \( f \) on a subspace of \( \mathcal{H} \). But while von Neumann’s theorem extends via Cesáro averages over Følner sets to amenable groups only, Theorem 1.9 holds for nonamenable groups as well.

Given an element \( p \in \beta G \), it is easy to see that \( R = p \cdot \beta G \) is a right ideal in \( \beta G \) (that is, \( R \cdot \beta G \subseteq R \)). By using Zorn’s lemma one can show that any right ideal contains a minimal ideal. It is also not hard to prove that any minimal right ideal in a compact left topological semigroup is closed.
Now, by Ellis’ theorem, any minimal ideal in $\beta G$ contains an idempotent. Idempotents belonging to minimal ideals are called minimal. It is minimal idempotents which allow one to introduce a new characterization of weak mixing for general groups. Recall that a set $A \subseteq \mathbb{Z}$ is called syndetic if it has bounded gaps and piecewise-syndetic if it is an intersection of a syndetic set with a union of arbitrarily long intervals. The following definition extends these notions to general semigroups.

**Definition 1.10.** Let $G$ be a (discrete) semigroup.

(i) A set $A \subseteq G$ is called syndetic if for some finite set $F \subseteq G$, one has
$$
\bigcup_{a \in F} A a^{-1} = G.
$$

(ii) A set $A \subseteq G$ is piecewise syndetic if for some finite set $F \subseteq G$, the family
$$
\left\{ \left( \bigcup_{a \in F} A a^{-1} \right) a^{-1} : a \in G \right\}
$$
has the finite intersection property.

The following proposition establishes the connection between minimal idempotents and certain notions of largeness for subsets of $G$. It will be used below to give a new sense to the fact that for a weakly mixing action on a probability space $(X, \mathcal{B}, \mu)$, the set $R_A B$ is large for all $\varepsilon > 0$ and $A, B \in \mathcal{B}$.

**Theorem 1.11.** (see [Be3], Exercise 7) Let $G$ be a discrete semigroup and $p \in (\beta G, \cdot)$ a minimal idempotent. Then

(i) For any $A \in p$, the set $B = \{ g : Ag^{-1} \in p \}$ is syndetic.

(ii) Any $A \in p$ is piecewise syndetic.

(iii) For any $A \in p$, the set
$$
A^{-1} A = \{ x \in G : yx \in A \text{ for some } y \in A \}
$$
is syndetic. (Note that if $G$ is a group, then $A^{-1} A = \{ g_1^{-1} g_2 : g_1, g_2 \in A \}.$)

**Definition 1.12.** A set $A \subseteq G$ is called central if there exists a minimal idempotent $p \in \beta G$ such that $A \in p$. A set $A \subseteq G$ is called a $C^*$-set (or central* set) if $A$ is a member of any minimal idempotent in $\beta G$.

**Remark 1.13.** The original definition of central sets (in $\mathbb{Z}$), which is due to Furstenberg (see [F2], p. 161), was the following: a subset $S \subseteq \mathbb{N}$ is a central set if there exists a system $(X, T)$, a point $x \in X$, a uniformly recurrent point $y$ proximal to $x$, and a neighborhood $U_y$ of $y$ such that $S = \{ n : T^nx \in U_y \}$. The fact that central sets can be equivalently defined as members of minimal idempotents was established in [BeH]. See also Theorem 3.6 in [Be3].

The following theorem gives yet another characterization of the notion of weak mixing.

**Theorem 1.14.** (see [Be3], Section 4) Let $(T_g)_{g \in G}$ be a measure preserving action of a countable group $G$ on a probability space $(X, \mathcal{B}, \mu)$. Then the following are equivalent:

(i) $(T_g)_{g \in G}$ is weakly mixing.

(ii) For every $f \in L^2(X, \mathcal{B}, \mu)$ and any minimal idempotent $p \in \beta G$, one has
$$
p-\lim_{g \in G} f(T_g x) = \int_X f d\mu \quad (\text{weakly}).
$$

(iii) There exists a minimal idempotent $p \in \beta G$ such that for any $f \in L^2(X, \mathcal{B}, \mu)$, one has
$$
p-\lim_{g \in G} f(T_g x) = \int_X f d\mu \quad (\text{weakly}).
$$

(iv) For any $A, B \in \mathcal{B}$ and any $\varepsilon > 0$, the set
$$
\{ g \in G : |\mu(A \cap T_g B) - \mu(A) \mu(B)| < \varepsilon \}
$$
is a $C^*$-set.
Given a weakly mixing action of, say, a countable (but not necessarily amenable) group $G$, one would like to know whether the action has higher order mixing properties along some massive and/or well-organized subsets of $G$. For example, it is not hard to show that for any weakly mixing $\mathbb{Z}$-action and any nonconstant polynomial $p(n) \in \mathbb{Z}[n]$, one can find an IP-set $S$ such that for any $A, B \in \mathcal{B}$, one has
\[
\lim_{n \to \infty, n \in S} \mu(A \cap T^{p(n)}B) = \mu(A)\mu(B).
\]
(An IP-set generated by a sequence $\{n_i: i \geq 1\}$ is, by definition, any set of the form $\{n_1 + \cdots + n_k: i_1 < \cdots < i_k; k \in \mathbb{N}\}$.)

Another example of higher degree mixing along structured sets is provided by a theorem proved in [BeRu], according to which any weakly mixing action of a countable infinite direct sum $G = \bigoplus_{n \geq 1} \mathbb{Z}_p$, where $\mathbb{Z}_p$ is the field of residues modulo $p$, has the property that the restriction of the action of $G$ to an infinite subgroup (which is isomorphic to $G$) is Bernoulli (see also [BeKM1], [BeKM2], [BeKLM], [JRW], [J], [B1]).

In Section 2 below we give a detailed analysis of higher order mixing properties for a concrete classical example — the standard action of $\text{SL}(2, \mathbb{Z})$ on the 2-dimensional torus $T^2$. Since $\text{SL}(2, \mathbb{Z})$ contains mixing automorphisms (namely, hyperbolic automorphisms), this action is weakly mixing. On the other hand, this action is not strongly mixing because $\text{SL}(2, \mathbb{Z})$ contains nontrivial unipotent elements.

While many of the results obtained below hold (sometimes, after an appropriate modification) for toral actions of $\text{SL}(n, \mathbb{Z})$ and even in more general situations, we intentionally deal here with $\text{SL}(2, \mathbb{Z})$-actions in order to make the paper more accessible and important issues more transparent.

Here is a sample of what is proved in the next section:

- (cf. Proposition 2.10) Let $T_1, \ldots, T_k \in \text{SL}(2, \mathbb{Z})$. Then the following assertions are equivalent:
  
  (i) For every $A_0, \ldots, A_k \in \mathcal{B}$,
  \[
  \mu(A_0 \cap T_1^{a_1}A_1 \cap \cdots \cap T_k^{a_k}A_k) \to \mu(A_0)\cdots\mu(A_k) \quad \text{as} \quad n \to \infty.
  \]
  
  (ii) Each $T_i$ is hyperbolic, $T_i \neq \pm T_j$ for $i \neq j$, and for every $p > 1$, there are at most two matrices among $T_i$, $i = 1, \ldots, k$, having an eigenvalue $\lambda$ such that $|\lambda| = p$.

- (cf. Proposition 2.20) Let $T_1, \ldots, T_k \in \text{SL}(2, \mathbb{Z})$ be hyperbolic automorphisms. Denote by $\lambda_i$ the eigenvalue of $T_i$ such that $|\lambda_i| > 1$. Put $a_{0,n} = 0$, $n \geq 1$. Let $k \geq 1$ and $a_{i,n} \in \mathbb{Z}$, $i = 1, \ldots, k$, be such that
  \[
  \min\{|\log|\lambda_i| \cdot a_{i,n} - \log|\lambda_j| \cdot a_{j,n}|: 0 \leq i < j \leq n\} \to \infty \quad \text{as} \quad n \to \infty.
  \]
  
  Then for every $A_0, \ldots, A_k \in \mathcal{B}$,
  \[
  \mu(A_0 \cap T_1^{a_{1,n}}A_1 \cap \cdots \cap T_k^{a_{k,n}}A_k) \to \mu(A_0)\cdots\mu(A_k) \quad \text{as} \quad n \to \infty.
  \]
  
  This result generalizes Rokhlin’s theorem [R] in the case of 2-dimensional torus. See also Proposition 2.24 for an analogue of this result for unipotent automorphisms.

- While every abelian group of automorphisms $G$, which acts in a mixing fashion on $T^2$, is mixing of order $k$ for every $k \geq 1$, (that is, for every $k \geq 1$ and sequences $g_{0,n} = e$, $g_{1,n}, \ldots, g_{k,n} \in G$ such that
  \[
  g_{i,n}^{-1}g_{j,n} \to \infty \quad \text{as} \quad n \to \infty \quad \text{for} \quad 0 \leq i < j \leq k,
  \]
  
  one has
  \[
  \mu(A_0 \cap g_{1,n}^{-1}A_1 \cap \cdots \cap g_{k,n}A_k) \to \mu(A_0)\cdots\mu(A_k) \quad \text{as} \quad n \to \infty
  \]
  
  a nonabelian group of automorphisms of $T^2$ is never mixing of order 2 (see Proposition 2.31). Note that there are nonabelian groups of automorphisms that act in a mixing fashion on $T^2$ (see the discussion after Proposition 2.30).
2. \textit{SL}(2,\mathbb{Z})\textendash \textit{ACTION ON TORUS}

\textbf{Definition 2.1.} A sequence $T_n \in \text{SL}(2,\mathbb{Z})$, $n \geq 1$, is called mixing if for every $f_1, f_2 \in L^\infty(T^2)$,
\begin{equation}
\int_{T^2} f_1(T_n \xi) f_2(\xi) d\xi \rightarrow \left( \int_{T^2} f_1(\xi) d\xi \right) \left( \int_{T^2} f_2(\xi) d\xi \right) \quad \text{as} \quad n \rightarrow \infty.
\end{equation}

A transformation $T \in \text{SL}(2,\mathbb{Z})$ is called mixing if the sequence $T^n$, $n \geq 1$, is mixing.

Note that this definition is different from the one given in [BBe].

Recall that a matrix $T$ is called hyperbolic if its eigenvalues have absolute values different from 1, and unipotent if all its eigenvalues are equal to 1. It is well-known that an automorphism $T \in \text{SL}(2,\mathbb{Z})$ is mixing on the torus $T^2$ if and only if it is hyperbolic. This implies that the action of $\text{SL}(2,\mathbb{Z})$ on $T^2$ is weakly but not strongly mixing and motivates the following problem: give necessary and sufficient conditions for a sequence $T_n \in \text{SL}(2,\mathbb{Z})$, $n \geq 1$, to be mixing.

We start with a useful and straightforward lemma (cf. Theorem 3.1(1) in [B2]). For a matrix $T$, denote by $T^t$ its transpose.

\textbf{Lemma 2.2.} A sequence $T_n \in \text{SL}(2,\mathbb{Z})$, $n \geq 1$, is mixing if and only if for every $(x, y) \in (\mathbb{Z}^2)^2 - \{(0, 0)\}$, the equality $T_n x + y = 0$ holds for finitely many $n$ only.

\textbf{Proof.} To prove that $T_n$ is mixing, it is sufficient to check (1) for $f_1$ and $f_2$ in the dense subspace of trigonometric polynomials. It follows that $T_n$ is mixing if and only if (1) holds for $f_1$ and $f_2$ that are characters of the form
\begin{equation}
\chi_n(\xi) = e^{2\pi i (x_n, \xi)}, \quad x \in \mathbb{Z}^2, \xi \in T^2.
\end{equation}

For $x, y \in \mathbb{Z}^2$, one has
\begin{equation}
\int_{T^2} \chi_n(T_n \xi) \chi_n(\xi) d\xi = \int_{T^2} \chi_n(t_{n+1} \xi) \chi_n(\xi) d\xi = \begin{cases} 0 & \text{if } T_n x + y \neq 0, \\ 1 & \text{if } T_n x + y = 0. \end{cases}
\end{equation}

It follows that for $(x, y) \in (\mathbb{Z}^2)^2 - \{(0, 0)\}$,
\begin{equation}
\int_{T^2} \chi_n(T_n \xi) \chi_n(\xi) d\xi \rightarrow \left( \int_{T^2} \chi_n(\xi) d\xi \right) \left( \int_{T^2} \chi_n(\xi) d\xi \right) = 0 \quad \text{as} \quad n \rightarrow \infty
\end{equation}
if and only if the equality $T_n x + y = 0$ holds for finitely many $n$ only. This proves the lemma. \hfill \Box

Denote by $M(2, \mathbb{K})$ the set of $2 \times 2$-matrices over a field $\mathbb{K}$. Using Lemma 2.2, we can now prove the following proposition.

\textbf{Proposition 2.3.} Let $T_n \in \text{SL}(2,\mathbb{Z})$, $n \geq 1$, $\| \cdot \|$ be the max-norm on $M(2, \mathbb{R})$, and $\mathcal{D} \subset M(2, \mathbb{R})$ denote the set of limit points of the sequence $\frac{T_n}{\|T_n\|}$ as $n \rightarrow \infty$. Then the sequence $T_n$ is not mixing if and only if there exist $A \in M(2, \mathbb{Q})$ and $B \in M(2, \mathbb{Q})$ such that $B \in \mathcal{D}$ and $T_n = A + \|T_n\| B$ for infinitely many $n \geq 1$.

\textbf{Proof.} We may assume that $\|T_n\| \rightarrow \infty$. (Indeed, if $\|T_n\| \rightarrow \infty$, then there exists a matrix $T_0$ such that $T_n = T_0$ for infinitely many $n$, and the statement is obvious.)

“$\Rightarrow$”: Let $T_n = A + \|T_n\| B$. Since
\begin{equation}
\det B = \lim_{n \rightarrow \infty} \det \left( \frac{T_n}{\|T_n\|} \right) = \lim_{n \rightarrow \infty} \frac{1}{\|T_n\|^2} = 0,
\end{equation}
$B$ is degenerate. Thus, there exists $x \in \mathbb{Z}^2 - \{0\}$ such that $T_n x = 0$. Then for infinitely many $n$, $T_n x = T_0 x$, and, by Lemma 2.2, $T_n$ is not mixing.

“$\Leftarrow$”: By Lemma 2.2, there exists $(x, y) \in (\mathbb{Z}^2)^2 - \{(0, 0)\}$ such that $T_n x = -y$ for infinitely many $n$. By passing, if needed, to a subsequence, we may assume that this equality holds for all $n \geq 1$. It is clear that $\gcd(x_1, x_2) = \gcd(y_1, y_2)$. Thus, we may assume that $x$ and $y$ are \textit{primitive} (that is, the $\gcd$...
of their coordinates is 1). Take $C, D \in \text{SL}(2, \mathbb{Z})$ such that $Ce_1 = x$ and $De_1 = -y$ where $e_1 = (1, 0)$. Then
\[ T_n = D \left( \begin{array}{cc} 1 & a_n \\ 0 & 1 \end{array} \right) C^{-1} = DC^{-1} + a_n D \left( \begin{array}{cc} 0 & 1 \\ 0 & 0 \end{array} \right) C^{-1} \]
for some $a_n \in \mathbb{Z}$. Put $'F_1 = DC^{-1}$ and $'F_2 = D \left( \begin{array}{cc} 0 & 1 \\ 0 & 0 \end{array} \right) C^{-1}$. We have
\[ T_n = F_1 + a_n F_2, \]
and
\[ |a_n| \cdot \|F_2\| - \|F_1\| \leq \|T_n\| \leq |a_n| \cdot \|F_2\| + \|F_1\|. \]
Hence, $\|T_n\| \sim |a_n| \cdot \|F_2\|$ as $n \to \infty$. Replacing, if necessary, $F_2$ by $-F_2$ and $a_n$ by $-a_n$ we may assume that $a_n > 0$ for infinitely many $n$. Then $B \overset{\text{def}}{=} \frac{F_2}{\|F_2\|} \in \mathcal{D}$. Passing to a subsequence, we get that $a_n > 0$ for $n \geq 1$. By triangle inequality and (4),
\[ \left\| T_n - \|T_n\| \frac{F_2}{\|F_2\|} \right\| \leq \left\| T_n - a_n F_2 \right\| + \left\| a_n F_2 - \|T_n\| \frac{F_2}{\|F_2\|} \right\| = \|F_1\| + |a_n| \|F_2\| - \|T_n\| \leq 2\|F_1\|. \]
Thus, for infinitely many $n$, $T_n - \|T_n\| B = A$ for some $A \in \text{M}(2, \mathbb{Q})$. This proves the proposition. \qed

We illustrate the usefulness of Proposition 2.3 by the following two propositions.

**Proposition 2.4.** Let $U, V \in \text{SL}(2, \mathbb{Z})$ be unipotent matrices. Then the sequence $T_n = U^{-n}V^n$ is mixing if and only if $UV \neq VU$.

**Proof.** If $U$ and $V$ commute, one can show that they are powers of a single unipotent transformation. Hence, in this case, the sequence $T_n = U^{-n}V^n$ is not mixing.

Conversely, suppose that $UV \neq VU$. There exist $A, B \in \text{SL}(2, \mathbb{Z})$ such that
\[ U = A^{-1} \left( \begin{array}{cc} 1 & u \\ 0 & 1 \end{array} \right) A \quad \text{and} \quad V = B^{-1} \left( \begin{array}{cc} 1 & v \\ 0 & 1 \end{array} \right) B \]
for some $u, v \in \mathbb{Z} \setminus \{0\}$. It is sufficient to show that the sequence $S_n = AT_nB^{-1}$ is mixing. Let $AB^{-1} = \left( \begin{array}{cc} a & b \\ c & d \end{array} \right)$. We have
\[ S_n = \left( \begin{array}{cc} 1 & -nu \\ 0 & 1 \end{array} \right) AB^{-1} \left( \begin{array}{cc} 1 & nv \\ 0 & 1 \end{array} \right) = \left( \begin{array}{cc} a - (cu)n & b - (av + du)n - (cv)n^2 \\ c & d + (cv)n \end{array} \right). \]
When $c = 0$,
\[ V = B^{-1} \left( \begin{array}{cc} 1 & v \\ 0 & 1 \end{array} \right) B = B^{-1}(AB^{-1})^{-1} \left( \begin{array}{cc} 1 & v \\ 0 & 1 \end{array} \right) (AB^{-1})B = A^{-1} \left( \begin{array}{cc} 1 & v \\ 0 & 1 \end{array} \right) A, \]
and it follows that $U$ and $V$ commute. Thus, $c \neq 0$.

We apply now Proposition 2.3. For sufficiently large $n$, $\|S_n\| = |b - (av + du)n - (cv)n^2|$. Also
\[ S_n \|S_n\| \rightarrow \left( \begin{array}{cc} 0 & -\text{sign}(cv) \\ 0 & 0 \end{array} \right) \overset{\text{def}}{=} C. \]
Since $S_n - \|S_n\| C$ is not constant for infinitely many $n$, the sequence $S_n$ is mixing. \qed

**Remark 2.5.** When $U, V \in \text{SL}(2, \mathbb{Z})$ are commuting unipotent transformations, the sequence $U^{-n}V^n$ is relatively mixing in the sense of Definition 2.22 below.

Using a similar argument, one proves the following proposition:

**Proposition 2.6.** Let $U, V \in \text{SL}(2, \mathbb{Z})$ such that $U$ is unipotent, and $V$ is hyperbolic. Then the sequence $T_n = U^{-n}V^n$ is mixing.
Proof. Denote by $E_{ij}$ the $2 \times 2$ matrix with 1 in position $(i, j)$ and 0’s elsewhere. For some $A, B \in \GL(2, \mathbb{R})$ and $\lambda$ with $|\lambda| > 1$,

$$U = A^{-1} \begin{pmatrix} \lambda & 0 \\ 0 & \lambda^{-1} \end{pmatrix} A \quad \text{and} \quad V = B^{-1} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} B.$$  

We write

$$T_n = A^{-1} \begin{pmatrix} \lambda^{-n} & 0 \\ 0 & \lambda^{n} \end{pmatrix} AB^{-1} \begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix} B = \lambda^{-n}C + \lambda^{-n}nD + \lambda^nE + \lambda^n nF$$

where

$$C = A^{-1} E_{11} A, \quad D = A^{-1} E_{11} A B^{-1} E_{12} B, \quad E = A^{-1} E_{22} A, \quad F = A^{-1} E_{22} A B^{-1} E_{12} B.$$  

Suppose that $F \neq 0$. Then $\frac{F}{\|F\|} \rightarrow \frac{E}{\|E\|}$. By Proposition 2.3, we need to show that there is no $X \in \M(2, \mathbb{R})$ such that $T_n - \|T_n\| \frac{E}{\|E\|} = X$ for infinitely many $n$. Since $F$ is degenerate, one of the matrices $C, D, E$ is not a scalar multiple of $F$ (say $C$). Take a basis of $\M(2, \mathbb{R})$ which contains $C$ and $F$. The $C$-coordinate of $T_n - \|T_n\| \frac{E}{\|E\|}$ with respect to this basis is equal to $\lambda^{-n} + \alpha \lambda^{-n} + \beta \lambda^n$ for some $\alpha, \beta \in \mathbb{R}$. This shows that the sequence $T_n - \|T_n\| \frac{E}{\|E\|}$ consists of distinct matrices for sufficiently large $n$. Thus, $T_n$ is mixing.

Suppose that $F = 0$. Then $\frac{F}{\|F\|} \rightarrow \frac{E}{\|E\|}$. By the same argument as in the previous paragraph, the sequence $T_n - \|T_n\| \frac{E}{\|E\|}$ consists of distinct matrices for sufficiently large $n$. This implies that $T_n$ is mixing. \hfill \square

Remark 2.7. When $U, V \in \SL(2, \mathbb{Z})$ are hyperbolic and $U \neq V$, the sequence $U^{-n}V^n$ is mixing. This follows from Proposition 2.10 below.

Next, we study multiple mixing for general sequences.

Definition 2.8. Let $T_{n,i} \in \SL(2, \mathbb{Z}), n \geq 1, i = 1, \ldots, k$. The sequences $T_{1,1}, \ldots, T_{k,n}$ are jointly mixing if for every $f_i \in L^\infty(T^2)$, $i = 1, \ldots, k + 1$,

$$\int_{T^2} f_1(T_{1,1}(\xi)) \cdots f_k(T_{k,n}(\xi)) d\xi d\eta \rightarrow \left(\int_{T^2} f_1(\xi) d\xi\right) \cdots \left(\int_{T^2} f_k(\xi) d\xi\right)$$

as $n \to \infty$. Transformations $T_{1,1}, \ldots, T_{k,k}$ are called jointly mixing if the sequences $T_{1,1}^{n}, \ldots, T_{k,k}^{n}, n \geq 1$, are jointly mixing.

In [B2], this property was called w-jointly strongly mixing (see Definition 3.6 in [B2]).

In the course of proving Proposition 2.10 below, we shall need the following immediate extension of Lemma 2.2 (cf. Theorem 4.3.1 in [B2]).

Lemma 2.9. Let $T_{n,i} \in \SL(2, \mathbb{Z}), n \geq 1, i = 1, \ldots, k$. The sequences $T_{1,1}, \ldots, T_{k,n}$ are jointly mixing if and only if for every $(x_1, \ldots, x_{k+1}) \in (\mathbb{Z})^{k+1} - \{(0, \ldots, 0)\}$ the equality

$$T_{1,n} x_1 + \cdots + T_{k,n} x_k + x_{k+1} = 0$$

holds for finitely many $n$ only.

Proposition 2.10. Let $T_i \in \SL(2, \mathbb{Z}), i = 1, \ldots, k$. The transformations $T_1, \ldots, T_k$ are jointly mixing if and only if each of $T_i$ is hyperbolic, $T_i \neq \pm T_j$ for $i \neq j$, and for every $p > 1$, there are at most two matrices among $T_i, i = 1, \ldots, k$, having an eigenvalue $\lambda$ such that $|\lambda| = p$.

Proof. If a matrix $T \in \SL(2, \mathbb{Z})$ has complex eigenvalues, they are units in an imaginary quadratic field. This implies that the eigenvalues of $T$ are roots of unity. Hence, the transformation $T$ is not mixing on $T^2$. Therefore, we may assume that the eigenvalues of $T$ are real.

Next, we note that one can assume without loss of generality that the eigenvalues of $T_i, i = 1, \ldots, k$, are positive. Indeed, put $T_i = -T_i$ if the eigenvalues of $T_i$ are negative and $T_i$ otherwise. Clearly, $T_i$, $i = 1, \ldots, k$, are jointly mixing if and only if transformations $T_i, i = 1, \ldots, k$, are jointly mixing.

Let the transformations $T_1, \ldots, T_k$ be jointly mixing. Then each of the sequences $T^n$ and $T_{-n}^n$, $i \neq j$, is mixing too. This implies that all $T_i$ are hyperbolic and $T_i \neq T_j$ for $i \neq j$. To show that the conditions of the theorem are necessary, we consider transformations $T_1, T_2, T_3 \in \text{SL}(2, \mathbb{Z})$ that have the same eigenvalue $\lambda > 1$. We claim that there exists $(x_1, x_2, x_3) \in \{z^2 \}^3 - \{(0, 0, 0)\}$ such that

\[
T^n x_1 + T_{-n}^n x_2 + T_{-n}^n x_3 = 0
\]

for every $n \geq 1$, which, in view of Lemma 2.9, implies that the sequences $T^n, T_{-n}^n, T_{-n}^n$ are not jointly mixing.

Since $T_i, i = 1, 2, 3$, have the same eigenvalues, there exist $A, B \in \text{GL}(2, \mathbb{R})$ such that

\[
T_2 = A^{-1} T_1 A \quad \text{and} \quad T_3 = B^{-1} T_1 B.
\]

Note that the matrix $A$ is a solution of the matrix equation

\[
XT_2 = T_1 X,
\]

which can be rewritten as a homogeneous system of linear equations with rational coefficients. The set of rational solutions of (8) is dense in the space of real solutions. It follows that there exists a rational solution (8) such that $\det(X) \neq 0$. This shows that we may choose $A$ and $B$ in $\text{GL}(2, \mathbb{Q})$.

For every $v \in \mathbb{R}^3$, $v = v_+ + v_-$ where $v_+$ and $v_-$ are eigenvectors of $T_1$ with eigenvalues $\lambda$ and $\lambda^{-1}$ respectively ($\lambda > 1$). Define linear maps $P_+: v \mapsto v_+$ and $P_-: v \mapsto v_-$. Then

\[
T_1 = \lambda P_+ + \lambda^{-1} P_- \quad \text{and} \quad P_+ P_- = P_- P_+ = 0, \quad P_+^2 = P_+, \quad P_-^2 = P_-.
\]

Note that $P_+, P_- \in M(2, \mathbb{Q}(\sqrt{d}))$ for some $d \in \mathbb{N}$ determined by $\lambda$. When $\sqrt{d} \in \mathbb{Q}$, $\lambda$ and $\lambda^{-1}$ are algebraic integers in $\mathbb{Q}$, and it follows that that $\lambda = \pm 1$, which is a contradiction. Thus, $\sqrt{d} \notin \mathbb{Q}$.

Denote by $\sigma$ the nontrivial Galois automorphism of the field extension $\mathbb{Q}(\sqrt{d})/\mathbb{Q}$. Then $\lambda^\sigma = \lambda^{-1}$ and $(P_+)^\sigma = P_-$. Using (7) and (9), we may rewrite equation (6) as

\[
\lambda^n (P_+ x_1 + \lambda P_+ A^{-1} x_2 + \lambda^{-1} B P_+ B^{-1} x_3) + \lambda^{-n} (P_- x_1 + \lambda^{-1} P_- A^{-1} x_2 + \lambda B P_- B^{-1} x_3) = 0.
\]

The columns of the matrices $P_+, \lambda P_+ A^{-1}$, and $\lambda^{-1} B P_+ B^{-1}$ lie in the vector space $\mathbb{Q}(\sqrt{d})^2$ that has dimension 4 over $\mathbb{Q}$. Thus, these columns are linearly dependent over $\mathbb{Q}$, and there exists $(x_1, x_2, x_3) \in \{z^2 \}^3 - \{(0, 0, 0)\}$ such that

$P_+ x_1 + \lambda P_+ A^{-1} x_2 + \lambda^{-1} B P_+ B^{-1} x_3 = 0$.

Applying $\sigma$ to this equality, we get

$P_- x_1 + \lambda^{-1} P_- A^{-1} x_2 + \lambda B P_- B^{-1} x_3 = 0$.

This implies (6) and proves that the conditions in the proposition are necessary for mixing.

To prove sufficiency consider $S_i, T_i \in \text{SL}(2, \mathbb{Z})$, $i = 1, \ldots, k$, such that $S_i$ and $T_i$ have the same eigenvalue $\lambda_i > 1$, and $\lambda_i < \lambda_j$ for $i < j$. We need to show that the transformations $S_1, T_1, \ldots, S_k, T_k$ are jointly mixing. By Lemma 2.9, it is enough to prove that there is no $(x_1, y_1, \ldots, x_k, y_k, z) \in \{z^2 \}^{2k+1} - \{(0, 0, 0, \ldots, 0)\}$ such that

\[
S^n_1 x_1 + T^n_1 y_1 + \cdots + S^n_k x_k + T^n_k y_k + z = 0.
\]

holds for infinitely many $n \geq 1$. Suppose that such a $(2k+1)$-tuple exists. Without loss of generality, we may assume that $y_k \neq 0$. As above, we define $P_{\pm}, Q_{\pm} \in M(2, \mathbb{R})$ such that

\[
S_i = \lambda_i P_{\pm} + \lambda_i^{-1} P_{-\pm}, \quad P_{\pm} + P_{-\pm} = P_{-\pm} P_{\pm} = 0, \quad P_{\pm}^2 = P_{\pm}, \quad P_{\pm} + P_{-\pm} = \text{id};
\]

\[
T_i = \lambda_i Q_{\pm} + \lambda_i^{-1} Q_{-\pm}, \quad Q_{\pm} + Q_{-\pm} = Q_{-\pm} Q_{\pm} = 0, \quad Q_{\pm}^2 = Q_{\pm}, \quad Q_{\pm} + Q_{-\pm} = \text{id}.
\]

Then (10) can be rewritten as

\[
\sum_{i=1}^k \lambda_i^{-n} (P_{\pm} x_i + Q_{\pm} y_i) + \sum_{i=1}^k \lambda_i^n (P_{\pm} x_i + Q_{\pm} y_i) + z = 0.
\]
Dividing this equality by $\lambda_k^q$ and taking a limit over a subsequence $n_j \to \infty$, we deduce that

$$P_{k,+}x_k + Q_{k,+}y_k = 0.$$ 

Suppose that $Q_{k,+}y_k = 0$. Then $y_k \neq 0$ is a rational eigenvector of $S_k$ with eigenvalue $\lambda_k^{-1}$. It follows that $\lambda_k, \lambda_k^{-1} \in \mathbb{Q}$. On the other hand, $\lambda_k$ and $\lambda_k^{-1}$ are algebraic integers. Hence, $\lambda_k = \pm 1$, which is a contradiction. This shows that

$$v \equiv P_{k,+}x_k = -Q_{k,+}y_k \neq 0.$$ 

We have

$$S_kv = \lambda_k v = T_kv.$$ 

As above, we denote by $\sigma_k$ the nontrivial automorphism of the quadratic extension $\mathbb{Q}(\lambda_k)/\mathbb{Q}$. Then

$$P_{k,+}^{\sigma_k} = P_{k,-}, \quad Q_{k,+}^{\sigma_k} = Q_{k,-}, \quad \lambda_k^{\sigma_k} = \lambda_k^{-1},$$

and it follows that

$$S_k^{\sigma_k}v = \lambda_k^{-1}v = T_k^{\sigma_k}v.$$ 

Since $v$ and $v^{\sigma_k}$ are linearly independent, this implies that $S_k = T_k$, which is a contradiction. Thus, (10) holds for finitely many $n$ only. The proposition is proved. \qed

Proposition 2.10 shows, in particular, that transformations $T_1, T_2, T_3 \in \text{SL}(2, \mathbb{Z})$ need not be jointly mixing even when every two of them are jointly mixing. Nonetheless, pairwise conditions are sufficient to imply mixing in the commutative situation.

**Proposition 2.11.** Let $T_1, \ldots, T_k \in \text{SL}(2, \mathbb{Z})$ be commuting automorphisms of $T^2$. Then they are jointly mixing if and only if the transformations $T_i$ and $T_i^{-1}T_j$, $i \neq j$, are mixing.

**Proof.** It is clear that if $T_1, \ldots, T_k$ are jointly mixing, then $T_i$ and $T_i^{-1}T_j$, $i \neq j$, are mixing.

Conversely, suppose that $T_i$ and $T_i^{-1}T_j$, $i \neq j$, are mixing. Then $T_i \neq \pm T_j$ for $i \neq j$. Since $T_i$ and $T_j$ commute and are hyperbolic, they can be simultaneously reduced to the diagonal form. Thus, if $T_i$ and $T_j$ have the same eigenvalues of the same modulus, then $T_i = \pm T_j$. It follows that the conditions of Proposition 2.10 are satisfied and hence, $T_1, \ldots, T_k$ are jointly mixing. \qed

One can show that the natural analog of Proposition 2.11 holds in every dimension.

In the case of a single measure preserving transformation $T$, $T$ is mixing if and only if for every $k \geq 1$, the transformation $T^k$ is mixing. In the following proposition, we investigate what happens for general sequences in our group:

**Proposition 2.12.** Let $T_n \in \text{SL}(2, \mathbb{Z})$, $n \geq 1$, be hyperbolic automorphisms. Let $\lambda_n$ be the eigenvalue of $T_n$ with $|\lambda_n| > 1$.

1. For any $k \geq 1$, if the sequence $\lambda_n$ is bounded, then $T_n$ is mixing if and only if $T_n^k$ is mixing.

2. For any $k \geq 2$, if $\lambda_n \to \infty$, the sequence $T_n^k$ is always mixing.

**Proof.** Let $t_n = \text{Trace}(T_n)$. Then $t_n$ is a root of its characteristic polynomial $x^2 - t_nx + 1$. Using the polynomial identity:

$$x^k = P(x)(x^2 - t_nx + 1) + \alpha_{n,k}x + \beta_{n,k}$$

where $\alpha_{n,k}, \beta_{n,k} \in \mathbb{Z},$

$$\alpha_{n,k} = \frac{\lambda_n^k - \lambda_n^{-k}}{\lambda_n - \lambda_n^{-1}}, \quad \beta_{n,k} = \frac{\lambda_n^{-k+1} - \lambda_n^{-1}}{\lambda_n - \lambda_n^{-1}},$$

we deduce that

$$T_n^k = \alpha_{n,k}T_n + \beta_{n,k}.$$ 

Suppose that $\lambda_n, n \geq 1$, is bounded. Then the sequences $\alpha_{n,k}$ and $\beta_{n,k}$ are bounded, hence take on only finitely many values. Hence, the equality

$$T_n^k x + y = T_n(\alpha_{n,k}x + (\beta_{n,k}x + y) = 0$$
holds for some \((x, y) \in (\mathbb{Z}^2)^2 - \{(0, 0)\}\) and infinitely many \(n\) if and only if the equality \(T_n x' + y' = 0\) holds for some \((x', y') \in (\mathbb{Z}^2)^2 - \{(0, 0)\}\) and infinitely many \(n\). By Lemma 2.2, this proves the first part of the proposition.

We assume now that \(\lambda_n \to \infty\). Then
\[
\alpha_{n,k} \sim \lambda_n^{k-1} \quad \text{and} \quad \beta_{n,k} \sim -\lambda_n^{k-2} \quad \text{as} \quad n \to \infty.
\]

By Lemma 2.2, it is sufficient to show that if (12) holds for infinitely many \(n\), then \(x = y = 0\). Suppose that (12) holds for infinitely many \(n\). Dividing by \(\alpha_{n,k}\) and taking a limit over a subsequence \(n_j \to \infty\), we conclude that \(T_{n_j} x \to 0\). Since the sequence \(T_{n_j} x\) is discrete, it follows that \(x = 0\), and \(y = 0\). Thus, \(T_n^k\) is mixing. \(\square\)

**Remark 2.13.** Note that the statement in part (2) of Proposition 2.12 fails for \(k = 1\). For example, let
\[
T_n = \begin{pmatrix} n & n-1 \\ 1 & 1 \end{pmatrix}, \quad n \geq 1,
\]
If \(\lambda_n\) denotes the largest eigenvalue of \(T_n\), then clearly, \(\lambda_n \to \infty\). However, the sequence \(T_n, n \geq 1\), is not mixing. (This follows from Proposition 2.3.)

Recall a theorem of Rokhlin [R]:

**Theorem 2.14. (Rokhlin)** Let \(T\) be a mixing automorphism of a compact abelian group. Then the sequences \(T^{a_1}, \ldots, T^{a_k}\) are jointly mixing provided that
\[
\min \{|a_{i,n} - a_{j,n}| : 0 \leq i < j \leq n\} \to \infty \quad \text{as} \quad n \to \infty,
\]
where \(a_{0,n} = 0\).

The following proposition shows that a naive generalization of Rokhlin’s theorem to a general sequence of automorphisms \(T_n\) is false.

**Proposition 2.15.** Let \(T_n \in \text{SL}(2, \mathbb{Z}), n \geq 1\). Denote by \(\lambda_n\) the eigenvalue of \(T_n\) such \(|\lambda_n| > 1\). If the sequence \(\lambda_n, n \geq 1\), is bounded, then for any choice of \(a_i \in \mathbb{Z}, i = 1, \ldots, k\) \((k > 1)\) the sequences \(T_n^{a_1}, \ldots, T_n^{a_k}\) are not jointly mixing.

**Proof.** Without loss of generality, we may assume that \(a_i > 0, i = 1, \ldots, k\).

By Lemma 2.9, it sufficient to show that there exists a tuple \((x_1, \ldots, x_{k+1}) \in (\mathbb{Z}^2)^{k+1} - \{(0, \ldots, 0)\}\) such that for infinitely many \(n\),
\[
T_n^{a_1} x_1 + \cdots + T_n^{a_k} x_k + x_{k+1} = 0.
\]

By (12), the last equality reduces to
\[
T_n (\beta_{n,a_1} x_1 + \cdots + \beta_{n,a_k} x_k) + \beta_{n,a_1} x_1 + \cdots + \beta_{n,a_k} x_k + x_{k+1} = 0.
\]

Since the sequence \(\lambda_n, n \geq 1\), is bounded, the sequences \(\alpha_{n,a_i}\) and \(\beta_{n,a_i}\) are bounded too. Thus, they are constant for infinitely many \(n\). Now one can easily choose \(x_i \in \mathbb{Z}^2, i = 1, \ldots, k+1\), not all zero, such that (13) holds. For example, one can take all \(x_i\)'s to be multiples a fixed nonzero integer vector. \(\square\)

**Remark 2.16.** Even if a sequence \(T_n \in \text{SL}(2, \mathbb{Z}), n \geq 1\), is such that
(i) \(T_n\) is hyperbolic and mixing on \(\mathbb{T}^2\) for all \(n\),
(ii) \(\lambda_n \to \infty\), where \(\lambda_n\) is the eigenvalue of \(T_n\) such that \(\lambda_n > 1\),
the sequences \(T_n^k\) and \(T_n^2\) need not be jointly mixing. For example, put

\[
T_n = \begin{pmatrix} n & n^2 - 1 \\ 1 & n \end{pmatrix}, \quad n \geq 1.
\]

Then \(T_n^2 x + T_n y + z = 0\) for \(x = '0, 1), y = '(-2, 0), z = '0, -2)\) which implies that the sequences \(T_n^2\) and \(T_n^2\) are not jointly mixing. On the other hand, it follows from Proposition 2.3 that the sequence
Proposition 2.17. Let $T_n \in SL(2, \mathbb{Z})$, $n \geq 1$. Denote by $\lambda_n$ the eigenvalue of $T_n$ such that $|\lambda_n| \geq 1$. Put $a_{i,n} = 0$, $n \geq 1$. Let $k \geq 1$ and $a_{i,n} \in \mathbb{Z}$, $i = 1, \ldots, k$. Denote

$$\gamma_n = \min\{|a_{i,n} - a_{j,n}| : 0 \leq i < j \leq n\}.$$ 

Suppose that one of the following conditions holds:

1. The sequence $T_n$ is mixing, and

$$\left\{ \frac{\|T_n\|}{\lambda_n^{\gamma_n}} : n \geq 1 \right\}$$

is bounded.

2. \( \frac{\|T_n\|}{\lambda_n^{\gamma_n}} \to 0 \quad \text{as} \quad n \to \infty. \)

Then the sequences $T_n^{a_{1,n}}, \ldots, T_n^{a_{k,n}}$ are jointly mixing.

Remark 2.18. Part (2) of the theorem with $T_n = T$, $n \geq 1$, implies Rokhlin’s theorem for the case of 2-dimensional torus.

Proof. Since $T_n$ is measure-preserving, we are allowed to replace $a_{i,n}$ by $a_{i,n} - \min\{a_{i,n} : i = 0, \ldots, k\}$. It follows that without loss of generality, we may assume that

$$\min\{a_{i,n} : i = 0, \ldots, k\} = 0.$$

Also by changing order and passing, if needed, to subsequences, we may assume that

$$\max\{a_{i,n} : i = 1, \ldots, k\} = a_{k,n}.$$

Suppose that the sequences $T_n^{a_{1,n}}, \ldots, T_n^{a_{k,n}}$ are not jointly mixing. By Lemma 2.9, there exists a tuple $(x_1, \ldots, x_{k+1}) \in (\mathbb{Z}^2)^{k+1} - \{(0, \ldots, 0)\}$ such that the equality

$$T_n^{a_{1,n}}x_1 + \cdots + T_n^{a_{k,n}}x_k + x_{k+1} = 0$$

holds for infinitely many $n$. By (11), the last equality is equivalent to

$$\sum_{i=1}^k \alpha_{n,a_{i,n}}T_nx_i + \sum_{i=1}^k \beta_{n,a_{i,n}}x_i + x_{k+1} = 0.$$

Note that in both cases, $\lambda_n^{\gamma_n} \to \infty$ as $n \to \infty$. Therefore, it follows that $\lambda_n^{a_{i,n} - a_{i,0}} \to \infty$.

$$\alpha_{n,a_{i,n}} \sim \frac{\lambda_n^{a_{i,n}}}{\lambda_n^{a_{i,0}}}, \quad \beta_{n,a_{i,n}} \sim \frac{\lambda_n^{a_{i,n}}}{\lambda_n^{a_{i,0}}}, \quad i = 1, \ldots, k.$$

Then

$$T_n^{a_{i,n}}x_k = -k \sum_{j=1}^{k-1} \frac{\alpha_{n,a_{i,j}}}{\alpha_{n,a_{i,n}}} T_n x_j - \sum_{j=1}^{k} \frac{\beta_{n,a_{i,j}}}{\alpha_{n,a_{i,n}}} x_j - \frac{x_{k+1}}{\alpha_{n,a_{i,n}}}. \quad \text{Since} \quad x_{k+1} \to 0.$$

Assume that condition (1) holds. Then the sequence $T_n^{a_{i,n}}x_k$ is bounded by infinitely many $n$. Thus, it is constant for infinitely many $n$. It follows from Lemma 2.2 that $x_k = 0$.

Suppose that condition (2) holds. We prove that $x_k = 0$. If $\lambda_n \to \infty$, then $T_n^{a_{i,n}}x_k \to 0$ as $n \to \infty$, and this implies that $x_k = 0$. Otherwise, the sequences $\lambda_n$ and $T_n^{a_{i,n}}x_k$ are bounded for infinitely many $n$, and consequently, they are constant for infinitely many $n$. Thus, $T_n^{a_{i,n}}x_k = \lambda_n^{-1}x_k$ for a subsequence.
and if \( x_t \neq 0 \), then \( \lambda_{n_j}, \lambda_{n_j}^{-1} \in \mathbb{Q} \). Since \( \lambda_{n_j} \) is an algebraic integer, \( \lambda_{n_j} = \pm 1 \), which contradicts condition (2). This shows that \( x_k = 0 \).

Now the proof can be completed by induction on \( k \).

**Remark 2.19.** Condition (1) is not necessary for joint mixing of the sequences \( T_n^{a_1,n}, \ldots, T_n^{a_k,n} \). For example, put

\[
T_n = \left( \begin{array}{cc} n^2 & n^3 - 1 \\ 1 & n \end{array} \right), \quad n \geq 1, \quad \text{and} \quad a_{i,n} = i, i = 1, 2.
\]

Even though \( \|T_n\| \to \infty \) as \( n \to \infty \), one can check with the help of Lemma 2.9 that the sequences \( T_n \) and \( T_n^2 \) are jointly mixing. It would be of interest to find a necessary and sufficient condition for joint mixing of sequences of the form \( T_n^{a_1,n}, \ldots, T_n^{a_k,n} \).

The following proposition is yet another generalization of Rokhlin’s theorem.

**Proposition 2.20.** Let \( T_1, \ldots, T_k \in \text{SL}(2, \mathbb{Z}) \) be hyperbolic automorphisms. Denote by \( \lambda_i \) the eigenvalue of \( T_i \) such that \( |\lambda_i| > 1 \). Put \( a_{0,n} = 0, \ n \geq 1 \). Let \( k \geq 1 \) and \( a_{i,n} \in \mathbb{Z}, \ i = 1, \ldots, k \) be such that

\[
\min \{ |\log |\lambda_i| \cdot a_{i,n} - \log |\lambda_j| \cdot a_{j,n}| : 0 \leq i < j \leq n \} \to \infty \quad \text{as} \quad n \to \infty.
\]

Then the sequences \( T_1^{a_1,n}, \ldots, T_k^{a_k,n} \) are jointly mixing.

**Proof.** As in the proof of Proposition 2.17, we reduce the proof to the case when

\[
\log |\lambda_i| \cdot a_{i+1,n} - \log |\lambda_i| \cdot a_{i,n} \to \infty \quad \text{as} \quad n \to \infty
\]

for \( i = 0, \ldots, k - 1 \).

Suppose that the sequences \( T_1^{a_1,n}, \ldots, T_k^{a_k,n} \) are not jointly mixing. By Lemma 2.9, there exists \( (x_1, \ldots, x_k, y) \in (\mathbb{Z}^*)^k \) such that the equality

\[
T_1^{a_1,n} x_1 + \cdots + T_k^{a_k,n} x_k + y = 0
\]

holds for infinitely many \( n \). Let \( P_{k+1}, P_{k-1} \in M(2, \mathbb{R}), \ i = 1, \ldots, k \), be such that

\[
T_i = \lambda_i P_{i+1} + \lambda_i^{-1} P_{i-1}, \quad P_{i+1} P_{i-1} = P_{i-1} P_{i+1} = 0, \quad P_{i}^2 = P_{i}, \quad P_{i+1} + P_{i-1} = \text{id}.
\]

By (15),

\[
\sum_{i=1}^{k} \lambda_i^{a_{i,n}} P_{i+1} x_i + \sum_{i=1}^{k} \lambda_i^{-a_{i,n}} P_{i-1} x_i + y = 0
\]

holds by infinitely many \( n \). Dividing by \( \lambda_k^{a_{k,n}} \) and taking limit over a subsequence \( n_j \to \infty \), we conclude that \( P_{k+1} x_k = 0 \).

If \( x_k \neq 0 \), it is an eigenvector of \( T_k \) with the eigenvalue \( \lambda_k^{-1} \). This implies that \( \lambda_k \in \mathbb{Q} \). On the other hand, \( \lambda_k \) is an algebraic integer. Thus, \( \lambda_k = \pm 1 \). This contradiction shows that \( x_k = 0 \). Using induction on \( k \), we deduce from (16) that \( x_i = 0 \) for \( i = 1, \ldots, k \). This shows that the sequences \( T_1^{a_1,n}, \ldots, T_k^{a_k,n} \) are jointly mixing.

**Remark 2.21.** It clear that condition (14) in Proposition 2.20 follows from the following condition:

\[
a_{i,n} \to \infty \quad \text{and} \quad \frac{a_{i+1,n}}{a_{i,n}} \to \infty, \quad i = 1, \ldots, k, \quad \text{as} \quad n \to \infty,
\]

which also appears in Proposition 2.24.

**Definition 2.22.** Let \( T_i \in \text{SL}(2, \mathbb{Z}), \ i = 1, \ldots, k \). Denote by \( P_i : L^2(T^2) \to L^2(T^2) \), \( i = 1, \ldots, k \), the orthogonal projection on the subspace of \( T_i \)-invariant functions. Let \( a_{i,n} \in \mathbb{Z}, \ i = 1, \ldots, k, \ n \geq 1 \). We call the sequences \( T_1^{a_1,n}, \ldots, T_k^{a_k,n} \) relatively jointly mixing if for every \( f_i \in L^\infty(T^2), \ i = 1, \ldots, k+1, \)

\[
\int_{T^2} f_1(T_1^{a_1,n} \xi) \cdots f_k(T_k^{a_k,n} \xi) f_{k+1}(\xi) d\xi \to \int_{T^2} (P_1 f_1)(\xi) \cdots (P_k f_k)(\xi) f_{k+1}(\xi) d\xi \quad \text{as} \quad n \to \infty.
\]
We have the following criterion for relative joint mixing of tuples of unipotent elements:

**Proposition 2.23.** Let $T_i \in \text{SL}(2, \mathbb{Z})$, $i = 1, \ldots, k$, be unipotent elements. Denote by $v_i$, $i = 1, \ldots, k$, a nonzero vector such that $T_i v_i = v_i$. Let $a_{i,n} \in \mathbb{Z}$, $i = 1, \ldots, k$, $n \geq 1$. Then the sequences $T_1^{a_{1,n}}, \ldots, T_k^{a_{k,n}}$ are relatively jointly mixing if and only if for every $(\alpha_1, \ldots, \alpha_k) \in \mathbb{Z}^k - \{(0, \ldots, 0)\}$ and $z \in \mathbb{Z}^2 - \{0\}$, the equality

$$
\sum_{i=1}^{k} \alpha_i a_{i,n} v_i + z = 0
$$

holds for finitely many $n$ only.

**Proof.** For some $A_i \in \text{SL}(2, \mathbb{Z})$ and $s_i \in \mathbb{Z} - \{0\}$,

$$
T_i^{a_{i,n}} = A_i^{-1} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} A_i = E + s_i a_{i,n} B_i
$$

where $B_i = A_i^{-1} \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} A_i \in \text{SL}(2, \mathbb{Z})$, and $E$ is the identity matrix. To establish relative mixing, it is sufficient to check (17) in the case when $f_i, i = 1, \ldots, k$, are characters of the form (2). For $x_1, \ldots, x_{k+1} \in \mathbb{Z}^2$, one has

$$
\int_{T^2} \chi_j (T_1^{a_{1,n}} x_1) \cdots \chi_k (T_k^{a_{k,n}} x_k) \chi_{k+1} (\xi) d\xi = \int_{T^2} \chi_j (T_1^{a_{1,n}} x_1 + \cdots + T_k^{a_{k,n}} x_k) \chi_{k+1} (\xi) d\xi = \left\{ \begin{array}{ll} 1 & \text{if } T_1^{a_{1,n}} x_1 + \cdots + T_k^{a_{k,n}} x_k + x_{k+1} = 0, \\
0 & \text{if } T_1^{a_{1,n}} x_1 + \cdots + T_k^{a_{k,n}} x_k + x_{k+1} \neq 0. \end{array} \right.
$$

Note that for every $x \in \mathbb{Z}^2$,

$$
P_i \chi_i = \left\{ \begin{array}{ll} \chi_i & \text{if } B_i x = 0, \\
0 & \text{if } B_i x \neq 0. \end{array} \right.
$$

Thus, (17) always holds for $f_i = \chi_j$ provided that $B_i x_i = 0$ for all $i = 1, \ldots, k$. It follows that the sequences $T_1^{a_{1,n}}, \ldots, T_k^{a_{k,n}}$ are relatively jointly mixing if and only if for every $(x_1, \ldots, x_k) \in (\mathbb{Z}^2)^k$ such that for some $i = 1, \ldots, k$, $B_i x_i \neq 0$ (equivalently, $T_i x_i \neq x_i$) the equality

$$
T_1^{a_{1,n}} x_1 + \cdots + T_k^{a_{k,n}} x_k + x_{k+1} = 0
$$

holds for finitely many $n$ only. By (19), the last equality is equivalent to

$$
\sum_{i=1}^{k} s_i a_{i,n} B_i x_i + z = 0
$$

where $z = \sum_{i=1}^{k+1} x_i$. Note that the columns of the matrix $B_i$ are rational multiples of the vector $v_i$. Thus, $s_i B_i x_i = \alpha_i v_i$ for some $\alpha_i \in \mathbb{Q}$. Since $B_i x_i \neq 0$ for some $i$, $(\alpha_1, \ldots, \alpha_k) \neq (0, \ldots, 0)$. This shows that (20) holds if and only if

$$
\sum_{i=1}^{k} \alpha_i a_{i,n} v_i + z = 0
$$

for some $(\alpha_1, \ldots, \alpha_k) \in \mathbb{Q}^k - \{(0, \ldots, 0)\}$ and $z \in \mathbb{Z}$. Multiplying by a fixed integer, we get that $\alpha_i \in \mathbb{Z}$. This proves the proposition. \[\square\]

We record here a convenient corollary of Proposition 2.23.

**Proposition 2.24.** Let $T_i \in \text{SL}(2, \mathbb{Z})$, $i = 1, \ldots, k$, be unipotent elements, and $a_{i,n} \in \mathbb{Z}$, $i = 1, \ldots, k$, $n \geq 1$, such that

$$
a_{1,n} \to \infty \quad \text{and} \quad \frac{a_{i+1,n}}{a_{i,n}} \to \infty, \quad i = 1, \ldots, k, \quad \text{as} \quad n \to \infty.
$$
Then the sequences $T_1^{a_1n}, \ldots, T_k^{a_kn}$ are relatively jointly mixing.

**Proof.** Suppose that the sequences $T_1^{a_1n}, \ldots, T_k^{a_kn}$ are not relatively jointly mixing. Then by Proposition 2.23, (18) holds for infinitely many $n$. Dividing (18) by $a_{kn}$ and taking the limit over a subsequence $n_k \to \infty$, we deduce that $a_k = 0$. Similarly, it follows that $a_i = 0$ for $i = 1, \ldots, k$. This shows that the sequences $T_1^{a_1n}, \ldots, T_k^{a_kn}$ are relatively jointly mixing. □

Let $T, S \in \text{SL}(d, \mathbb{Z})$. It was observed by Boshernitzan that it follows from the fact that the set of common periodic points of $T$ and $S$ is dense in $\mathbb{T}^d$ that for every nonempty open subset $\mathcal{U}$ of $\mathbb{T}^d$,

$$\mathcal{U} \cap T^n \mathcal{U} \cap S^n \mathcal{U} \neq \emptyset$$

for infinitely many $n$. A measurable analogue of this fact is far less trivial. The following conjecture seems plausible:

**Conjecture 2.25.** Let $T, S \in \text{SL}(d, \mathbb{Z})$, and let $\mathcal{D}$ be a Borel subset of $\mathbb{T}^d$ of positive measure. Then

$$\limsup_{n \to \infty} \mu(\mathcal{D} \cap T^n \mathcal{D} \cap S^n \mathcal{D}) > 0.$$ 

In fact, in all known to us examples,

$$\limsup_{n \to \infty} \mu(\mathcal{D} \cap T^n \mathcal{D} \cap S^n \mathcal{D}) \geq \mu(\mathcal{D})^3.$$ 

**Remark 2.26.** Note that when $T$ and $S$ generate a (virtually) nilpotent group, Conjecture 2.25 follows from a general "nilpotent" multiple recurrence theorem proved in [L] (see also Theorem E in [BelL2]). It was, however, proved in [BelL3], that for any finitely generated solvable group of exponential growth $G$, there exist a measure preserving action $(T_g)_{g \in G}$ on a probability space $(X, \mathcal{B}, \mu)$, elements $g_1, g_2 \in G$ and a set $D \in \mathcal{B}$ with $\mu(D) > 0$ such that for $T = T_{g_1}$ and $S = T_{g_2}$, one has

$$\mu(D \cap T^n D \cap S^n D) = 0 \text{ for all } n \neq 0.$$ 

Nevertheless, we believe that for our special action of $\text{SL}(d, \mathbb{Z})$ on $\mathbb{T}^d$, the Conjecture is true.

We obtain below some partial results on the conjecture in the case of the 2-dimensional torus. Note that when $T$ and $S$ are hyperbolic the conjecture follows from Proposition 2.10. In fact, in this case,

$$\lim_{n \to \infty} \mu(\mathcal{D} \cap T^n \mathcal{D} \cap S^n \mathcal{D}) = \begin{cases} \mu(\mathcal{D})^2 & \text{if } T = S, \\ \mu(\mathcal{D})^3 & \text{if } T \neq \pm S \end{cases}$$ 

and when $T = -S$, the limit set of the sequence $\mu(\mathcal{D} \cap T^n \mathcal{D} \cap S^n \mathcal{D})$ consists of two numbers: $\mu(\mathcal{D})^2$, $\mu(\mathcal{D} \cap -D)\mu(D)$. In particular, this shows that $\liminf$ might be 0 even when $\mu(\mathcal{D}) > 0$.

We can also settle the case when $T$ and $S$ are unipotent and hyperbolic respectively. For this, we need a lemma:

**Lemma 2.27.** Let $T \in \text{SL}(2, \mathbb{Z})$ be unipotent, and $S \in \text{SL}(2, \mathbb{Z})$ hyperbolic. Then the sequences $T^n$ and $S^n$, $n \geq 1$, are relatively jointly mixing.

**Proof.** As in the proof of Proposition 2.23, it is sufficient to show that for every $x, y, z \in \mathbb{Z}^2$ such that either $Tx \neq x$ or $y \neq 0$, the equality

$$t^n x + S^n y + z = 0$$

holds for finitely many $n$ only. We have

$$t^n = E + nB$$

where $E$ is the identity matrix and $B \in M(2, \mathbb{Z})$. Let $\lambda$ be the eigenvalue of $S$ such that $|\lambda| > 1$. For some $P_+, P_- \in M(2, \mathbb{Z})$,

$$t^n = \lambda^n P_+ + \lambda^{-n} P_-, \quad P_+ P_- = P_- P_+ = 0, \quad P_{\pm}^2 = P_\pm, \quad P_+ + P_- = \text{id.}$$

Equality (21) is equivalent to

$$\lambda^n P_+ y + \lambda^{-n} P_- y + nBx + (x + z) = 0.$$
Suppose that it holds for infinitely many $n$. Dividing by $\lambda^n$ and taking the limit as $n \to \infty$, we deduce that $P_n y = 0$. Then $y$ is an eigenvector of $S$. If $y \neq 0$, then $y$ is a rational eigenvector of $S$, and $\lambda$ and $\lambda^{-1}$ are rational numbers that are algebraic integers. Hence, $\lambda = \pm 1$, which is a contradiction. This implies that $y = 0$. Then it follows that $Bx = 0$ (equivalently, $Tx = x$). This shows that (21) holds for finitely many $n$ only. Thus, the sequences $T^n$ and $S^n$, $n \geq 1$, are relatively jointly mixing. \hfill \square

Lemma 2.27 implies the following special case of Conjecture 2.25.

**Proposition 2.28.** Let $T \in \text{SL}(2, \mathbb{Z})$ be unipotent, and $S \in \text{SL}(2, \mathbb{Z})$ hyperbolic. Then for any measurable $D \subseteq \mathbb{T}^2$, the limit of $\mu(D \cap T^n D \cap S^n D)$ as $n \to \infty$ exists, and

$$\lim_{n \to \infty} \mu(D \cap T^n D \cap S^n D) \geq \mu(D)^3.$$

Moreover, the equality holds if and only if $\mu(D) = 1$ or $0$.

**Proof.** Let $f$ be the characteristic function of the set $D$. Denote by $P_T$ and $P_S$ the orthogonal projections on the the spaces of $T$- and $S$-invariant functions respectively. Since $S$ is ergodic, $P_S f = \mu(D)$. By Lemma 2.27,

$$\lim_{n \to \infty} \mu(D \cap T^n D \cap S^n D) = \int_{\mathbb{T}^2} f(P_T f)(P_S f) d\mu = \mu(D)\|P_T f\|_2^2 \geq \mu(D)^3.$$

In the case when $T$ and $S$ are unipotent, Conjecture 2.25 seems to be open in general. We prove a partial result for sets of special form. For a function $f \in L^2(\mathbb{T}^d)$, its Fourier coefficients are denoted by

$$\hat{f}(\xi) = \int_{\mathbb{T}^d} f(x)\chi_{\xi} (x) d\xi, \quad x \in \mathbb{Z}^d.$$

**Proposition 2.29.** Let $T, S \in \text{SL}(2, \mathbb{Z})$ be unipotent.

1. For any measurable $D \subseteq \mathbb{T}^2$, the limit of $\mu(D \cap T^n D \cap S^n D)$ as $n \to \infty$ exists.
2. Suppose that $TS \neq ST$. Let $A \in \text{SL}(2, \mathbb{Z})$ be such that $A^{-1}TA$ is lower triangular unipotent. Then for every set of the form $D = A(D_1 \times D_2)$ where $D_1$ and $D_2$ are measurable subsets of $\mathbb{T}^1$,

$$\lim_{n \to \infty} \mu(D \cap T^n D \cap S^n D) \geq \mu(D)^3.$$

Moreover, the equality holds if and only if $\mu(D) = 1$ or $0$.

**Proof.** We prove (1) in the case when $T$ and $S$ do not commute. (When $T$ and $S$ commute, they are powers of the same transformation, and the proof goes along the same lines as the proof below.)

Let $v$ and $w$ be primitive integer vectors such that $Tv = v$ and $Sw = w$. We claim that for $f, g, h \in C^\infty(\mathbb{T}^2)$,

$$\int_{\mathbb{T}^2} f(\xi) g(T^n \xi) h(S^n \xi) d\xi \to \sum_{i, j \in \mathbb{Z}} \hat{f}(-iv - jw) \hat{g}(iv) \hat{h}(jw) \quad \text{as} \quad n \to \infty. \quad (22)$$

It follows from a standard argument that it is sufficient to check (22) when $f, g, h$ are characters of the form (2).

Let $f = \chi_x$, $g = \chi_y$, and $h = \chi_z$ for some $x, y, z \in \mathbb{Z}^2$. First, suppose that $x = -iv - jw$, $y = iv$, $z = jw$ for some $i, j \in \mathbb{Z}^2$. Then

$$\int_{\mathbb{T}^2} f(\xi) g(T^n \xi) h(S^n \xi) d\xi = \int_{\mathbb{T}^2} \chi_x(T^{ni} S^{nj} \xi) d\xi = 1.$$

This implies (22) in this case.

Now we consider the case when $x, y, z$ are not of the above form. We need to show that the equality $x + T^y y + S^n z = 0$ holds for finitely many $n$ only. Suppose that it holds for infinitely many
Write $T = E + B$ and $S = E + C$ where $E$ is the identity matrix and $B, C \in \text{SL}(2, \mathbb{Z})$ such that $B^2 = C^2 = 0$. Then

$$x + T^n y + S^n z = (x + y + z) + n(By + Cz) = 0.$$ 

holds for infinitely many $n$. This implies that $x + y + z = 0$ and $By = -Cz$. Note that the columns of matrix $B$ are multiples of the vector $v$, and the columns of $C$ are multiples of $w$. If $By \neq 0$, $v$ is multiple of $w$, and it follows that in some basis of $\mathbb{R}^2$ both $T$ and $S$ are unipotent upper triangular. Then $TS = ST$, and this contradicts the initial assumption. Thus, $By = Cz = 0$. Equivalently, $Ty = y$ and $Sz = z$. Hence, $x = -iv - jv$, $y = iv$, and $z = jw$ for some $i, j \in \mathbb{Z}$. This is a contradiction. We have proved (22).

Replacing $T$ by $A^{-1}TA$ and $S$ by $A^{-1}SA$, we reduce the problem to the case when $T$ is lower triangular and $D = D_1 \times D_2$. Then $v = '1, 0)$. Let $w = 'a, b)$. Let $f$ be the characteristic function of the set $D_1$ and $f_1$ and $f_2$ be characteristic functions of the sets $D_1$ and $D_2$ respectively. Note that for $s, t \in \mathbb{Z}$, $f(s, t) = f_1(s)f_2(t)$. To prove part (2), we need to show that

$$\sum_{i, j \in \mathbb{Z}} \hat{f}(-i - aj, -bj)f(i, 0)\hat{f}(aj, bj) \geq \mu(D)^3.$$ 

Using the Plancherel formula and the fact that $f_j^2 = f_1$, we have

$$\sum_{i, j \in \mathbb{Z}} \hat{f}(-i - aj, -bj)f(i, 0)\hat{f}(aj, bj) = \sum_{j \in \mathbb{Z}} \left( \sum_{i \in \mathbb{Z}} \hat{f}_1(-aj - i)\hat{f}_1(i) \right) \hat{f}_2(-bj)\hat{f}_2(0)\hat{f}(aj, bj)$$

$$= \sum_{j \in \mathbb{Z}} (\hat{f}_2(j))(-aj)\hat{f}_2(-bj)\mu(D_2)\hat{f}(aj, bj)$$

$$= \mu(D_2) \sum_{j \in \mathbb{Z}} |\hat{f}_1(aj)|^2|\hat{f}_2(bj)|^2$$

$$\geq \mu(D_2)|\hat{f}_1(0)|^2|\hat{f}_2(0)|^2 \geq \mu(D)^3.$$ 

We are done. 

Next, we investigate mixing properties of subgroups of $\text{SL}(2, \mathbb{Z})$.

**Proposition 2.30.** Let $H$ be a subgroup of $\text{SL}(2, \mathbb{Z})$. The action of $H$ on $\mathbb{T}^2$ is mixing if and only if $H$ contains no nontrivial unipotent elements.

**Proof.** If the action of $H$ is mixing, then the action of every infinite subgroup of $H$ is mixing, and consequently, $H$ does not contain nontrivial unipotent elements.

Conversely, suppose that the action of $H$ is not mixing. By Lemma 2.2, there exists a sequence $h_n \in H$, $n \geq 1$, and $(x, y) \in (\mathbb{Z}^2)^2 - \{(0, 0)\}$ such that $h_n x = -y$ for every $n \geq 1$ and $h_n \to \infty$. Then $h_n h_n^{-1} h_n x = x$ for every $n \geq 1$. Thus, $h_n h_n^{-1} \in H$ is a nontrivial unipotent element for sufficiently large $n$. This proves the proposition. 

A subgroup of $\text{SL}(2, \mathbb{Z})$ is called nonparabolic if it contains no nontrivial unipotent elements. Nonparabolic subgroups are of interest from the point of view of ergodic theory because they are precisely the groups that act in a mixing fashion on the torus $\mathbb{T}^2$. It follows from the pigeonhole principle that every subgroup of $\text{SL}(2, \mathbb{Z})$ of finite index contains a nontrivial unipotent element. First examples of nonparabolic subgroups were constructed by B. H. Neumann in [N] (see also [Mas]). Any Neumann subgroup has the property that powers of a single unipotent element form a complete system of representatives of the cosets of this group. In particular, Neumann subgroups are maximal nonparabolic subgroups. There are examples of maximal nonparabolic subgroups that are not Neumann (see [T], [BrL1], [BrL2]). If $F$ is a free normal subgroup of finite index in $\text{SL}(2, \mathbb{Z})$ which is not equal to the commutant of $\text{SL}(2, \mathbb{Z})$, then the commutant of $F$ is nonparabolic (see [Mas]).
Although there are large subgroups in $\text{SL}(2, \mathbb{Z})$ (e.g. Neumann subgroup) whose actions on the torus $\mathbb{T}^2$ are mixing, the following proposition shows that for nonabelian subgroups the higher order of mixing is impossible.

**Proposition 2.31.** A nonabelian subgroup of $\text{SL}(2, \mathbb{Z})$ cannot be mixing of order 2.

**Proof.** Let $H$ be a nonabelian subgroup of $\text{SL}(2, \mathbb{Z})$. Suppose that $H$ is mixing of order 2. Take $g, h \in H$ such that $gh \neq hg$. Since $H$ is mixing, $g$ and $h$ are hyperbolic. Note that if $g^2 h = hg^2$, $g^2$ and $h$ can be both reduced to the diagonal form, and this would imply that $g$ and $h$ commute. Thus, $g^2 h \neq hg^2$. Put $h_i = g^{-i} h g^i$, $i = 1, 2, 3$. Comparing eigenvalues, we deduce that $h_i \neq h_j$. Also, $h_i \neq h_j$ for $i \neq j$, since otherwise it would follow that $g$ and $h$ commute. Therefore, by Proposition 2.10, the transformations $h_i$ and $h_j$ are jointly mixing for $i \neq j$. In particular, $h_i^{-n} h_j^n \to \infty$ and $h_i^n \to \infty$ as $n \to \infty$. On the other hand, since $h_1$, $h_2$, $h_3$ have the same eigenvalues, it follows from Proposition 2.10 (and its proof) that for some $f_1, f_2, f_3 \in L^2(\mathbb{T}^2)$,

$$\lim_{n \to \infty} \int_{\mathbb{T}^2} f_1(h_1^n \xi) f_2(h_2^n \xi) f_3(h_3^n \xi) d\xi \neq \int_{\mathbb{T}^2} f_1(\xi) d\xi \int_{\mathbb{T}^2} f_2(\xi) d\xi \int_{\mathbb{T}^2} f_3(\xi) d\xi.$$

This implies that the sequences $h_1^{-n} h_2^n$ and $h_1^n h_3^{-n}$ are not jointly mixing, which, in its turn, contradicts the assumption that the group $H$ is mixing of order 2. \hfill $\Box$

More generally, a similar argument allows one to show that the standard action on the torus $\mathbb{T}^d$ of a subgroup $H$ of $\text{SL}(d, \mathbb{Z})$ which is not virtually abelian cannot be mixing of order $d$. Another approach to the proof of this fact can be found in [Bh] where it is utilized for derivation of isomorphism rigidity for the action of $H$.

**Remark 2.32.** It should be noted that in contrast with the nonabelian situation, any mixing $\mathbb{Z}^d$ action on $\mathbb{T}^d$ is mixing of all orders (see [S, Corollary 27.7]). On the other hand, if an $\text{SL}(d, \mathbb{Z})$-action is a restriction of an ergodic measure preserving $\text{SL}(d, \mathbb{R})$-action, then by a theorem of S. Mozes (see [Moz]), it is mixing of all orders.

We conclude by proving a result of Krengel-type [Kr], which can be considered as a generalization of the fact that every ergodic automorphism of the torus has countable Lebesgue spectrum.

**Proposition 2.33.** Let $H$ be a subgroup of $\text{SL}(2, \mathbb{Z})$ which acts in mixing fashion on $\mathbb{T}^2$. Then for every $f \in L^2(\mathbb{T}^2)$ and every $\varepsilon > 0$, there exist $f_0 \in L^2(\mathbb{T}^2)$ and a subgroup $H_0$ of finite index in $H$ such that

$$\int_{\mathbb{T}^2} f_0(h \xi) \bar{f}_0(\xi) d\xi = 0$$

for every $h \in H_0$, $h \neq e$.

**Proof.** First, we note that since $H$ is mixing, for every $(x, y) \in (\mathbb{Z}^2)^2 - \{(0, 0)\}$ there is at most one $h$ such that $h x = y$. Indeed, if $h_1 x = h_2 x$ for some $h_1, h_2 \in H$, then $h_1 h_2^{-1} \in H$ is a unipotent element.

One can choose

$$f_0 = \sum_{i=1}^{m} a_i x_i$$

with some $a_i \in \mathbb{C}$ and $x_i \in \mathbb{Z}^2$ such that $\|f - f_0\|_2 < \varepsilon$. We have

$$\int_{\mathbb{T}^2} f_0(h \xi) \bar{f}_0(\xi) d\xi = \sum_{i,j=1}^{m} a_i \bar{a}_j \int_{\mathbb{T}^2} x_i x_{i-j}(\xi) d\xi.$$

Let $h_{ij} \in H - \{e\}$ be the unique element such that $h_{ij} x_i = x_j$ (if such an element exists). Since $\text{SL}(2, \mathbb{Z})$ is finitely approximable, the subgroup $H$ is finitely approximable too. There exists a subgroup $H_0$ of finite index in $H$ such that $h_{ij} \notin H_0$ for every $i, j = 1, \ldots, m$. Then (23) holds for every $h \in H_0$, $h \neq e$. This proves the proposition. \hfill $\Box$
ACKNOWLEDGMENTS

We would like to thank D. Berend, N. Hindman, and R. Pavlov for useful comments on the preliminary version of the paper. We also would like to thank K. Schmidt for bringing Bhattacharya’s paper [Bh] to our attention.
